First paper to describe the Pennsylvanian conglomerates in Salt Valley

CARBONIFEROUS SYSTEM

PENNSYLVANIAN (?) SERIES

UNNAMED CONGLOMERATE

A conglomerate containing boulders of limestone and chert as much as 15 inches in diameter embedded in an indurated yellow sandstone matrix is exposed in two isolated areas in Salt Valley—one in sec. 15 and the other in secs. 9 and 10, T. 23 S., R. 20 E. The stratigraphic relations of the conglomerate have not been ascertained, owing to complicated structure and poor exposures. The boulders of the conglomerate contain fossils, all of which are regarded by G. H. Girty as either Mississippian or longer-ranging species that could be Mississippian. The list of forms identified from the first collections is given in another paper¹⁸ but is summarized here for completeness.

Triplophyllum, one or more species.
Fenestella, several species
Schuchertella aff. S. chemungensis
Schuchertella sp.
Productella aff. P. concentrica
Productus ovatus
Productus aff. P. fernglenensis
Rhipidomella aff. R. pulchella
Schizophoria sedaliensis?
Schizophoria sp.
Camarophoria bisinuata?
Camarotoechia aff. C. metallica

Camarotoechia sp.
Spiriferina solidirostris
Spiriferina sp.
Delthyris novamexicana?
Spirifer centronatus
Spirifer aff. S. centronatus
Spirifer sp.
Pseudosyrinx aff. P. keokuk
Cliothyridina? sp.
Composita humilis?
Composita? sp.

A collection made subsequently by E. T. McKnight contains the following species:

Triplophyllum sp.
Fenestella, several species
Schuchertella? sp.
Chonetes loganensis
Productus aff. P. burlingtonensis

Camarotoechia metallica
Aviculipecten sp.
Naticopsis sp.
Phillipsia sp.
Bairdia? sp.

These identifications were made by G. H. Girty, who says:

This collection, like the collections made at the same locality last year, is rather certainly of Mississippian age, probably Madison.

¹⁸ Baker, A. A., Dobbin, C. E., McKnight, E. T., and Reeside, J. B., Jr., Notes on the stratigraphy of the Moab region, Utah: Am. Assoc. Petroleum Geologists Bull., vol. 11, no. 8, pp. 789-790, 1927.

Boulders are up to 30 inches across

“complicated structure” – strata are locally vertical and recumbent

Limestone boulders have Mississippian fossils

Girty – Age of fossils -- “probably Madison” = Leadville Fm

The occurrence in the boulders of the conglomerate of fossils of Mississippian age proves only the post-Mississippian age of the rock, but the abundance of fossil-bearing boulders, the absence of boulders definitely identifiable as belonging to later rocks, and the fact that no comparable conglomerate has been discovered elsewhere in any formation cropping out in the region point together to an early age for the conglomerate. As Pennsylvanian rocks are abundantly exposed in the region, the conglomerate is presumably of early Pennsylvanian age, a conclusion a priori probable from its physical constitution and somewhat reinforced by the existence of the thin Molas formation in the San Juan Mountain region of Colorado.¹⁹ The Molas contains conglomerate beds, the boulders of which carry Mississippian fossils, and a scanty invertebrate fauna has been found in it that indicates its Pennsylvanian age and has some points of similarity with the more abundant fauna found in the overlying Hermosa formation. The Molas rests upon an erosional unconformity cut on the underlying Leadville limestone, which is of lower Mississippian age and correlated with the Madison limestone. The outcrops in the San Juan Mountains are the nearest present-day outcrops from which the lower Mississippian boulders in the conglomerate in Salt Valley could have been derived, but the probability appears strong that the lower Mississippian limestone underlies a much wider area than its existing exposures would indicate and that the boulders were derived from some source exposed nearby at the time of deposition. As the Molas formation is only 40 to 50 feet thick, and there seems no reason to suppose a great thickness for a basal Pennsylvanian conglomerate, it appears possible that Mississippian limestone may exist at no great depth beneath the surface exposure of the conglomerate. However, the structural relations in the vicinity of the exposures are so complex that this must be regarded only as a possibility. This possibility, however, might appropriately be investigated by core drilling by any company interested in exploiting the possible oil resources of the region, the drilling to be regarded only as an attempt to obtain information on the lower part of the stratigraphic succession—information which might be of practical value in subsequent deep drilling elsewhere and would surely be of scientific interest.

“no comparable conglomerate has been discovered elsewhere in region” - still true today

“Molas Fm contains conglomerate beds” –

but,

Molas conglomerates are 130 miles SE in SW Colorado

“the boulders were derived from some source exposed nearby” –
closest logical source is 15 miles NE at the Uncompahgre Uplift

LATE PALEOZOIC AND EARLY MESOZOIC STRUCTURAL HISTORY OF
THE UNCOMPAHGRE FRONT¹

By
DONALD P. ELSTON and EUGENE M. SHOEMAKER
U. S. Geological Survey, Denver, Colorado
U. S. Geological Survey, Menlo Park, California

1960

This 1960 paper assigns conglomerates
in Salt Valley to the Permian Cutler Fm;
second paper in 1960 by authors says the same

*We were unable to find any later reference since 1960s
which re-describes the conglomerates
or suggests an age other than Permian.
Let us know if there was a new study!*

Structures shown do not fit observed dips in outcrops

Conglomerates are interbedded within Paradox Fm with Pennsylvanian fossils and evaporites – they are not surficial deposits

Vertical w/ recumbent folding and faults

Not Cutler Fm

Paradox Fm

Brushy Basin shak member of Hermose formation

UNCONFORMITY

Cutler (?) formation

Gray to brown conglomerate consisting of rounded pebbles, cobbles and boulders of limestone and dolomite cemented by fine- to coarse-grained quartz and calcite, slightly arkosic; on southwest, unit is brown fine- to coarse-grained conglomeratic sandstone containing scattered limestone pebbles

UNCONFORMITY

Paradox member of Hermose formation

Phpa-light- to dark-gray, carbonaceous, laminated, in part fissile, siltstone, silty claystone, and silty limestone

Phpb-light yellow-brown, thinly laminated to thinly bedded siltstone sandstone, thin beds of gray to brown aphanitic to finely crystalline, minor lenses of gypsum, and local bed of gypsum (stippled)

Phpc-light- to medium-gray, laminated to massive gypsum with interbedded medium dark-gray clayey siltstone

Phpd-gray limestone and interbedded clayey siltstone

Contact

Dashed where approximately located; short dashed for indefinite base of surficial deposits; dotted where restored on cross sections

Fault

Dashed where approximately located; dotted where concealed. U, upthrown side; D, downthrown side

Anticline

Showing trace of axial plane and bearing and plunge of axis. Dotted where concealed

Syncline

Showing trace of axial plane. Dotted where concealed
